Stethoscope

A stethoscope can be used to find mechanical noises and air leaks.

It is a more sensitive device than a stick or screwdriver.

For that reason, some remove the probe on the end and simply use the hose end for probing.

Then it's less strain on the ears.

Mechanic stethoscope. ¹⁾

The black partition at the end of the tape measure is where the diaphragm is. Note the size of the diaphragm.

Rubber Hose

This can be a spare piece of oil line or even a cut off piece of garden hose.

Hold one end up to your ear and the other end against the testing site.

Screwdriver

You can use a screwdriver as a listening device.

Grab a big (biggest you have) screwdriver from your toolbox. ²⁾

Put the metal end on the area you wish to listen to and your ear on the top of the handle.

Noise is transferred through the screwdriver to your ear.

Wooden Dowel / Stick

A wood stick transfers noises well.

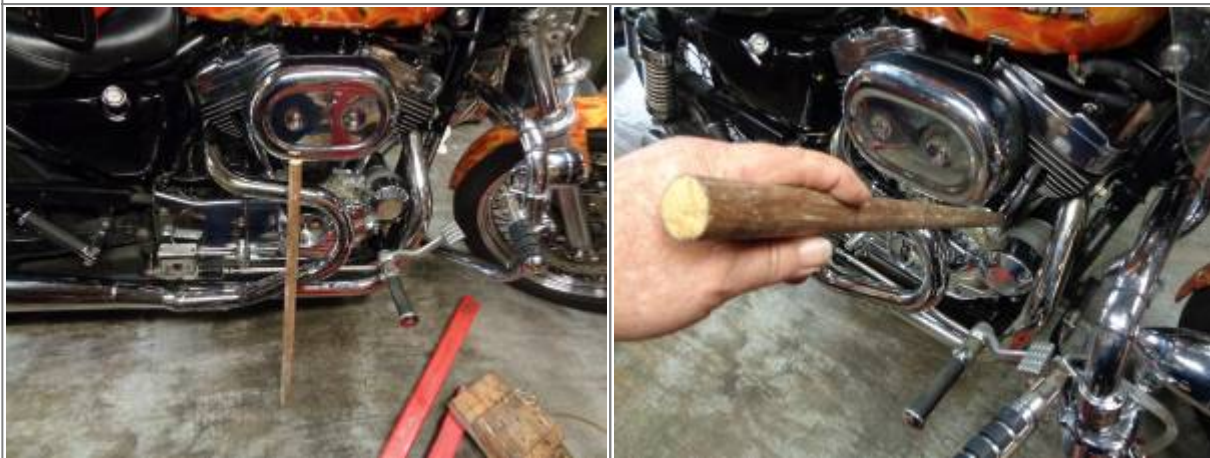

You can hear soft and loud noises as well as feel light ticking to hard knocking sounds.

A wooden handle screwdriver, hammer or a length of 2×4 will also work.

Place one end on the area you're listening to and the other to your ear.

Sound is transferred through the wood.

A wooden dowel for a listening tool. ³⁾
